WOT	Wide Open Throttle

3. Introduction

The goal of Work Package 6 (**WP6**) is to synthesise the knowledge gained during the project's experimental activities into potential new policies and regulations and to evaluate their possible future impact for the public health and wellbeing of citizens, as well as the social acceptance of the economic impacts that could derive from the new policies and regulations. Possible future policy scenarios include tyre airborne particle emissions (**Deliverable 6.1**), microplastics emissions (**Deliverable 6.2**), and tyre noise emissions (**Deliverable 6.3**).

The Commission's 2021 EU Action Plan, 'Towards Zero Pollution for Air, Water and Soil' aims to reduce pollution to levels that are no longer considered harmful to health and natural ecosystems. One of the 2030 key targets is to reduce the share of people who are chronically disturbed by transport noise by 30% compared to 2017.

Current automotive noise legislations define maximum noise emission limits that have to be complied with standardized pass-by noise test procedures. The currently applicable noise standards are UN R51, for vehicle pass-by noise, UN R117, for tyre noise, and Tyre Labelling (EU) 2020/740 which includes noise information for the consumers. Recently UN R138 introduced minimum sound levels for electric vehicles. A significant part of the overall pass-by noise test on a vehicle is will be caused by the tyres.

In this deliverable we went through the noise regulations for tyres, vehicles and electric vehicles. We collected measured data to assess current noise levels. We compared them with the literature. We collected data from EPREL and other databases and search for correlations between noise and other parameters such as wet grip, rolling resistance, abrasion and price. We developed a simplified model to estimate citizens' noise exposure and to assess various mitigation measures.

Two scenarios were considered in this Task 6.3 for tyre noise. The baseline scenario investigated the possible evolution of the problem assuming no policy changes. The second scenario examined the feasibility of imposing stringent tyre noise limits. The impact of the proposed scenarios on public health and well-being of citizens along with a cost-benefit analysis was examined and compared to the baseline scenario.

Note: The terms **noise** and **sound** are used interchangeable, even though GRBP decided to start using the term sound instead of noise after R 138.
We also use the terms **dB** and **dB(A)** interchangeably.

4. Regulatory requirements for vehicle and tyres sound emission

4.1. UN Reg. 51 (vehicles) – UN Reg. 117 (tyres)

Considering the tyre rolling sound emissions as one of the main contributors to the total vehicle sound emission, we can compare the testing conditions and limit values of both Regulations (Table 1 to Table 4) to have a better understanding of their impact on the actual real sound emission level.

Table 1 : Test conditions for vehicle sound of M1 and N1 categories and rolling sound of C1 and C2 tyres.

R51.03 Transitional provisions for new type approvals:

- | | | |
|----------|---|-------------|
| Phase 2: | Mandatory for vehicles other than N2: | 1 July 2020 |
| | Mandatory for vehicles N2: | 1 July 2022 |
| Phase 3: | Mandatory for vehicles other than N2, N3, M3: | 1 July 2024 |
| | Mandatory for vehicles N2, N3, M3: | 1 July 2026 |

It should be added that for M1, N1 and M2≤3500 kg category vehicles, the final value (L_{urban}) is a combination of two by pass conditions: wide open throttle (WOT) runs and constant speed runs (CSR). Both tests should be performed with the same gear ratio selection in case of manual gearbox. The final calculation is using a weighting factor (k_p)

$$L_{urban} = L_{wot} - k_p * (L_{wot} - L_{crs}),$$

$$k_p = 1 - (a_{urban} / a_{wot}),$$

$$a_{urban} = 0.63 * \log_{10}(PMR) - 0.09$$

Practically speaking L_{urban} will be L_{wot} with small correction down.

For M2>3500 kg, M3, N2, N3 category vehicles, $L_{urban} = L_{wot}$

4.2. UN Reg. 138

For quiet vehicles, in addition to the requirements stated in UN R51, the vehicle must meet the requirements of UN R138 as well, which are minimum sound emissions to alert pedestrians and other vulnerable road users about the presence of the vehicle (Table 5).

Table 5 : Minimum sound level requirements in dB(A).

The relevant EU regulations are Regulation (EU) 540/2014 for cars, vans, buses and trucks, Regulation (EU) 2019/2144 on type approval of road vehicles including tyre requirements, and Regulation (EU) 2020/740 on tyre labelling.

5. UN Reg. 51 type approval values

During the last 2 years (2023-2024) IDIADA as technical service designated by some type approval authorities has performed several official test for vehicle type approval according to R51.03.

The summary of the test results following Annex 3 are as follows (Table 6):

Table 6 : UN R51 Pass-by sound test results at IDIADA (2023-2024).

Tests: 5	Category	propulsion type	result pass-by dB(A)
	M1	ICE	71,0

	M3	ICE	77,0
	M3	ICE	78,0
	M3	ICE	73,0
	M3	ICE	76,0
	M3	ICE	76,0
	M3	ICE	78,0
	M3	ICE	74,0
	M3	ICE	77,0
	M3	ICE	75,0
Average:			76,1

D6.3 – Policies and mitigation strategies on tyre noise emissions

Tests: 6	Category	propulsion type	result pass-by dB(A)
	M3	BEV	64,0
	M3	BEV	77,0
	M3	BEV	69,0
	M3	BEV	68,0
	M3	BEV	65,0
	M3	BEV	74,0
	Average:		69,5
Tests: 1	Category	propulsion type	result pass-by dB(A)
	M3	FCEV	67,0
	Average:		67,0

Table 7 summarises the results. PEV compared to ICEs for M1 category had on average 5 dB(A) lower sound. For M3 category there was a high difference of 7-9 dB(A) between BEV/FCEVs and ICEs. However, for N2 category the difference was only 1.5 dB(A). Note that, at the time of testing, for most vehicles, the Phase 2 limits were applicable.

Table 7 : Summary of UN R51 test results at IDIADA (2023-2024).

Category	#	Propulsion type	Pass-by dB(A)
M1	5	ICE	71.2 (71.0-71.9)
M1	16	PEV	66.0 (64.0-68.0)
N1	4	ICE	72.8 (72.0-74.0)
N2	4	ICE	73.5 (73.0-74.0)
N2	2	PEV	72.0 (70.0-74.0)
N3	4	ICE	80.0 (79.0-81.0)
M3	20	ICE	76.1 (72.0-78.0)
M3	6	BEV	69.5 (64.0-77.0)
M3	1	FCEV	67.0

The Table 8 summarises the results from the 2022 ACEA report [1]. Although direct comparison is not possible as L_{Urban} values were reported, in general the agreement with IDIADA data is good considering also the different time periods (2020 vs 2024 IDIADA).

Table 8 : Overview of ACEA 2020 test results.

Category	#	Propulsion type	Pass-by dB(A)
M1 (L _{Urban})	1655 (all)	ICE	68 (64-74)
M1 (L _{Urban})	14	HEV	68 (64-71)
M1 (L _{Urban})	27	BEV	67 (64-69)
M2 (L _{Urban})	23	ICE	71.3 (69-75)
M3 (L _{Urban})	42 (+2 BEV)	ICE	73.5 (71-78)
N1	156	ICE	70.3 (66-74)
N1	3	BEV	69 (67-71)
N2	74 (+2 BEV around 69)	ICE	72.4 (67-78)
N3	119 (+2 HEV around 79)	ICE	79.3 (74-84)
N3	6	BEV	71.7 (69-76)

6.Tyre rolling sound contribution to total vehicle sound emissions

As stated before, the tyres are tested according to R117 Annex 3. The tests are performed at a range of speeds:

- (a) From 70 to 90 km/h for class C1 and class C2 tyres;
- (b) From 60 to 80 km/h for class C3 tyres.

The correlation between sound emission and vehicle speed is then calculated based on linear regression. That is allowing to extrapolate the sound emission at different vehicle speed such as R51 Annex 3 target speed. We have taken all tests performed at IDIADA according to R117 Annex 3 over the last 2 years (2023-2024) and based on each regression line, we have been able to extrapolate what would be the tyre rolling sound emission at vehicle target speed according to R51. A few tests at 50 km/h vehicle speed confirmed the relationship.

Figure 1 : Speed vs. tyre noise.

The following tables are showing the number of tests performed, the average tyre rolling sound emission at coast-by vehicle speed according to R117, the average of all calculated tyre rolling sound emission at vehicle speed according to R51:

Considering vehicle category:

- M1 will be equipped with C1 class tyres
- N1 will be equipped with C2 class tyres
- M2, M3, N2, N3 will be equipped with C3 tyres

D6.3 – Policies and mitigation strategies on tyre noise emissions

Table 9 : Tyre rolling sound emissions according to R117 at IDIADA

C1				
	# tests	80 km/h	50 km/h	50 km/h
2023	63	70,4	63,4	
2024	62	70,6	63,8	63,6

C2				
	# tests	80 km/h	50 km/h	50 km/h
2023	4	72,2	65,5	
2024	10	73,0	64,8	65,0

C3				
	# tests	70 km/h	35 km/h	35 km/h
2023	33	70,6	58,0	
2024	28	71,8	58,5	58,2

Considering that tyre rolling sound emission is just a part of the total vehicle sound emission, we could then use the commonly accepted approach for combined different sound emission sources:

$$dB_{total} = 10 \cdot \log_{10} \cdot (10^{dB1/10} + 10^{dB2/10} + \dots + 10^{dBn/10})$$

The calculated average sound emission of the non-tyre part for each vehicle category and propulsion technology will be as shown in the following table. Vehicle sound emission taken from [Chapter 5](#) (dB_{total}) and tyre sound emission taken from above table in this page (dB_1). We have then calculated non tyre sound (dB_2).

Table 10 : Contribution of tyre rolling noise to vehicle sound.

Vehicle sound	Tyre	Non tyre sound	Tyre sound	% tyre
71,2	C1	70,4	63,6	1,2%
66,0	C1	62,3	63,6	5,6%
72,8	C2	72,0	65,0	1,1%
73,5	C2	72,8	65,0	1,0%
72,0	C2	71,0	65,0	1,4%
80,0	C3	80,0	58,2	0,0%
76,1	C3	76,0	58,2	0,1%
69,5	C3	69,2	58,2	0,4%
67,0	C3	66,4	58,2	0,9%

We can also see the real contribution of the tyre rolling sound over the total vehicle sound emission as percentage in the last column.

7. Impact of road surface to tyre rolling sound emission

The GRBP set up the Task Force Measurement Uncertainties subgroup in 2019 to identify the different sources of variability on sound emission measurement, especially focused on R51 and R117.

After several analysis related to R117 Coast-by measured according to Annex 3, the following main categories of uncertainty were found as shown in the following Table 11.

We can see the test track surface is the highest one, even comparing among several test tracks approved according to ISO10844. In real roads the values should be higher.

Table 11 : Sources of uncertainty of sound measurements.

Uncertainty categories	Systematic or Random	Standard Uncertainty [dB] 95% confidence interval	Description
1 Test Repeatability (day by day)	Random	± 0.6 ^(b)	Result variability once tyres, track, acquisition system, vehicle and modus operandi are the same (Day and driver might be different)
1.1 Test Repeatability (run to run)	Random	± 0.3 ^(b)	Result variability for consecutive test once tyres, track, acquisition system, vehicle and modus operandi are the same
1.2 Track Humidity	Random	Unknown	Definition of "dry" is quite vague Humidity may affect more R51 Drive-by than R117
1.3 Speed effect	Random	± 0.13	Minimum requirement for sensor accuracy in R117 is +/- 1km/h- tyre noise vs speed sensitivity= 0.2 dB/km/h PtoP = 0.2 dB * 2km/h=0.4 dB (± 0.13)
1.4 Temperature influence (after temperature correction)	Random	± 0.3 ^(b)	Despite temperature correction a residual error remains (Formula not fully correct). Only applicable for C1/C2 tyres
2 Temperature influence (without temperature correction)	Systematic	± 0.6	The systematic error is removed in Reg.117 (except for C3) but not in Reg.51 Reg. 117 allows following temperature ranges: air 5>,<40 surface temperature >5,<50 Estimated peak to peak by Reg.117 formula = 1.8 dB (± 0.6 dB)
3 Track to Track	Systematic	± 1.8 ^(a)	Estimated by VDA round robin test results
4 Tyre to tyre	Random	± 0.5 ^(b)	Uncertainty due to production variability (Different plants, different period....) Excluding ageing effect
5 Sound meter-to sound meter	Random	± 0.4 ^(a)	Measurement system shall meet class 1 requirements
6 Vehicle influence	Systematic / Random	± 1.0 ^(b)	Possibility to use different vehicles. Uncertainty takes into consideration differences on: Wheel adjustment, Suspension, Tyre load and inflation, Body-road clearance, shadowing and reflecting properties, Rim, Transmission noise, Bearings, Brake noise (brakes not completely released), Body shape - aerodynamic noise around the vehicle body and extra equipment
Total Uncertainty C1/C2 tyres		± 2.2 dB	Combined standard uncertainty $U = \sqrt{(u_1^2 + u_3^2 + u_4^2 + u_5^2 + u_6^2)}$
Total Uncertainty C3 tyres		± 2.3 dB	Combined standard uncertainty $U = \sqrt{(u_1^2 + u_2^2 + u_3^2 + u_4^2 + u_5^2 + u_6^2)}$

According to European Tyre & Rubber Manufacturers Association (ETRMA), this variability means that a homologated value could be 2.3 dB higher or lower (with low probability<5%). ETRMA demonstrated that reducing the uncertainty to half would reduce tyres exceeding the limit due to the methodology uncertainties from 33% to 11% [2].

D6.3 – Policies and mitigation strategies on tyre noise emissions

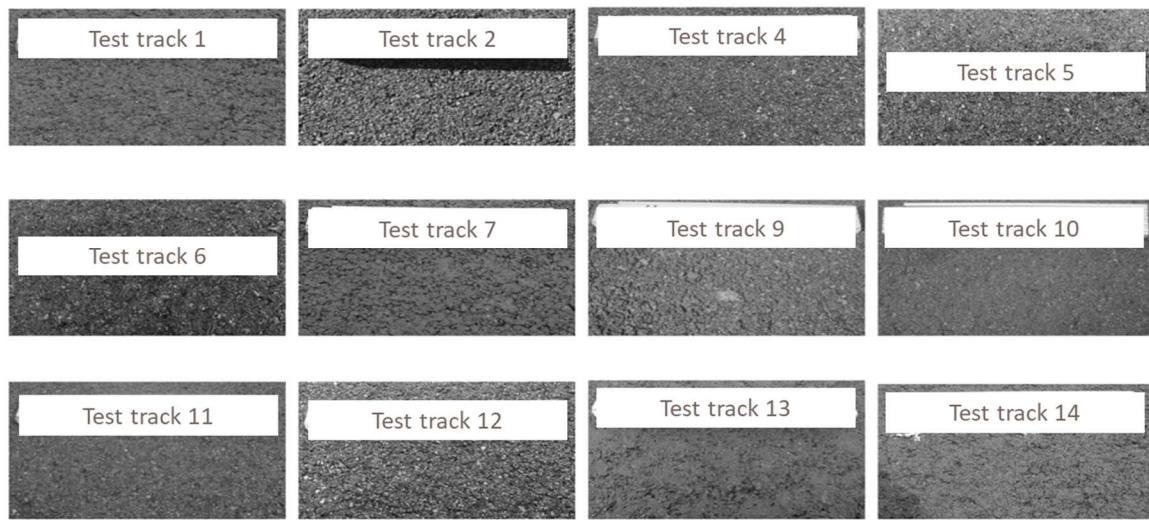

Figure 2 : Test track surfaces.

8. Study on label parameters

This chapter aims to verify whether there is any correlation between noise and the other parameters on the label, as well as interaction between noise levels and price.

8.1. Methodology

We considered the five best-selling sizes for each type of tyre (C1, C2 and C3) in order to extract a representative market sample and look for a correlation between the values of the labelling of the tyres, the rolling resistance (RR) and wet grip (WG) with the noise level. The most accurate tyre labelling data is EPREL. The size of the sample extracted was of 450 hundred tyres in total. 150 tyres per type of tyre, being 30 tyres per size. For the sample selection we considered several factors to ensure its representativeness. Firstly, we made sure that brands were not excessively repeated. Additionally, the percentage distribution of premium, mid-range, and low-cost tires for each size was adjusted to match the actual sales percentages in the market. We also ensured that the selected tires were verified in the EPREL database, as some tires uploaded to the platform still display an alert indicating they are pending verification. For each tyre, we provide the dimensions, brand, model, identifier, season (winter, non-winter), load index, and the labelling values (RR, WB, and Noise). All this information, as previously explained, was extracted from EPREL. The last two columns indicate the average European price of the tyre and the budget range. For the prices of C1 and C2 tyres, we consulted an international sales platform and calculated an average price for each tyre model. For C3 tyres, we consulted our list of 150 tyres with a supplier who has access to the average European prices for all models. In this case, the supplier informed us about models that were no longer sold or had been updated with improved properties, and we made the necessary adjustments accordingly. Table 12 shows a section of the list of tyres with the information explained above.

Table 12 : Overview of xls file with information collected.

	Dimensions	Brand	Model	Identifier	Winter	Std / Reinf.	RR	WG	Noise (dB)	Price (€)	Budget
1	205/55R16	Continental	EcoContact 6	314991	No	Std	A	B	71	89.5	Premium

8.2. Results

First of all, we looked for a correlation between noise and RR categories, and noise and WG categories for each type of tyre comparing all the data directly. The following graphics represent 150 tyres classified for each RR category (A, B, C, D or E) compared to its noise values generating an average box. The same is done with the WG category (A, B, C or D). We observed a tendency between the RR category and the noise level, but the same cannot be said for WG. However, no definitive conclusions can be drawn. To analyse this trend in greater detail, we classified the tyres by type (C1, C2, or C3), size, season (winter or non-winter), and RR or WG categories. We then calculated the average noise levels for each category to gain a clearer understanding of potential correlations. We also analysed the category prices to explore relationships between price and noise.

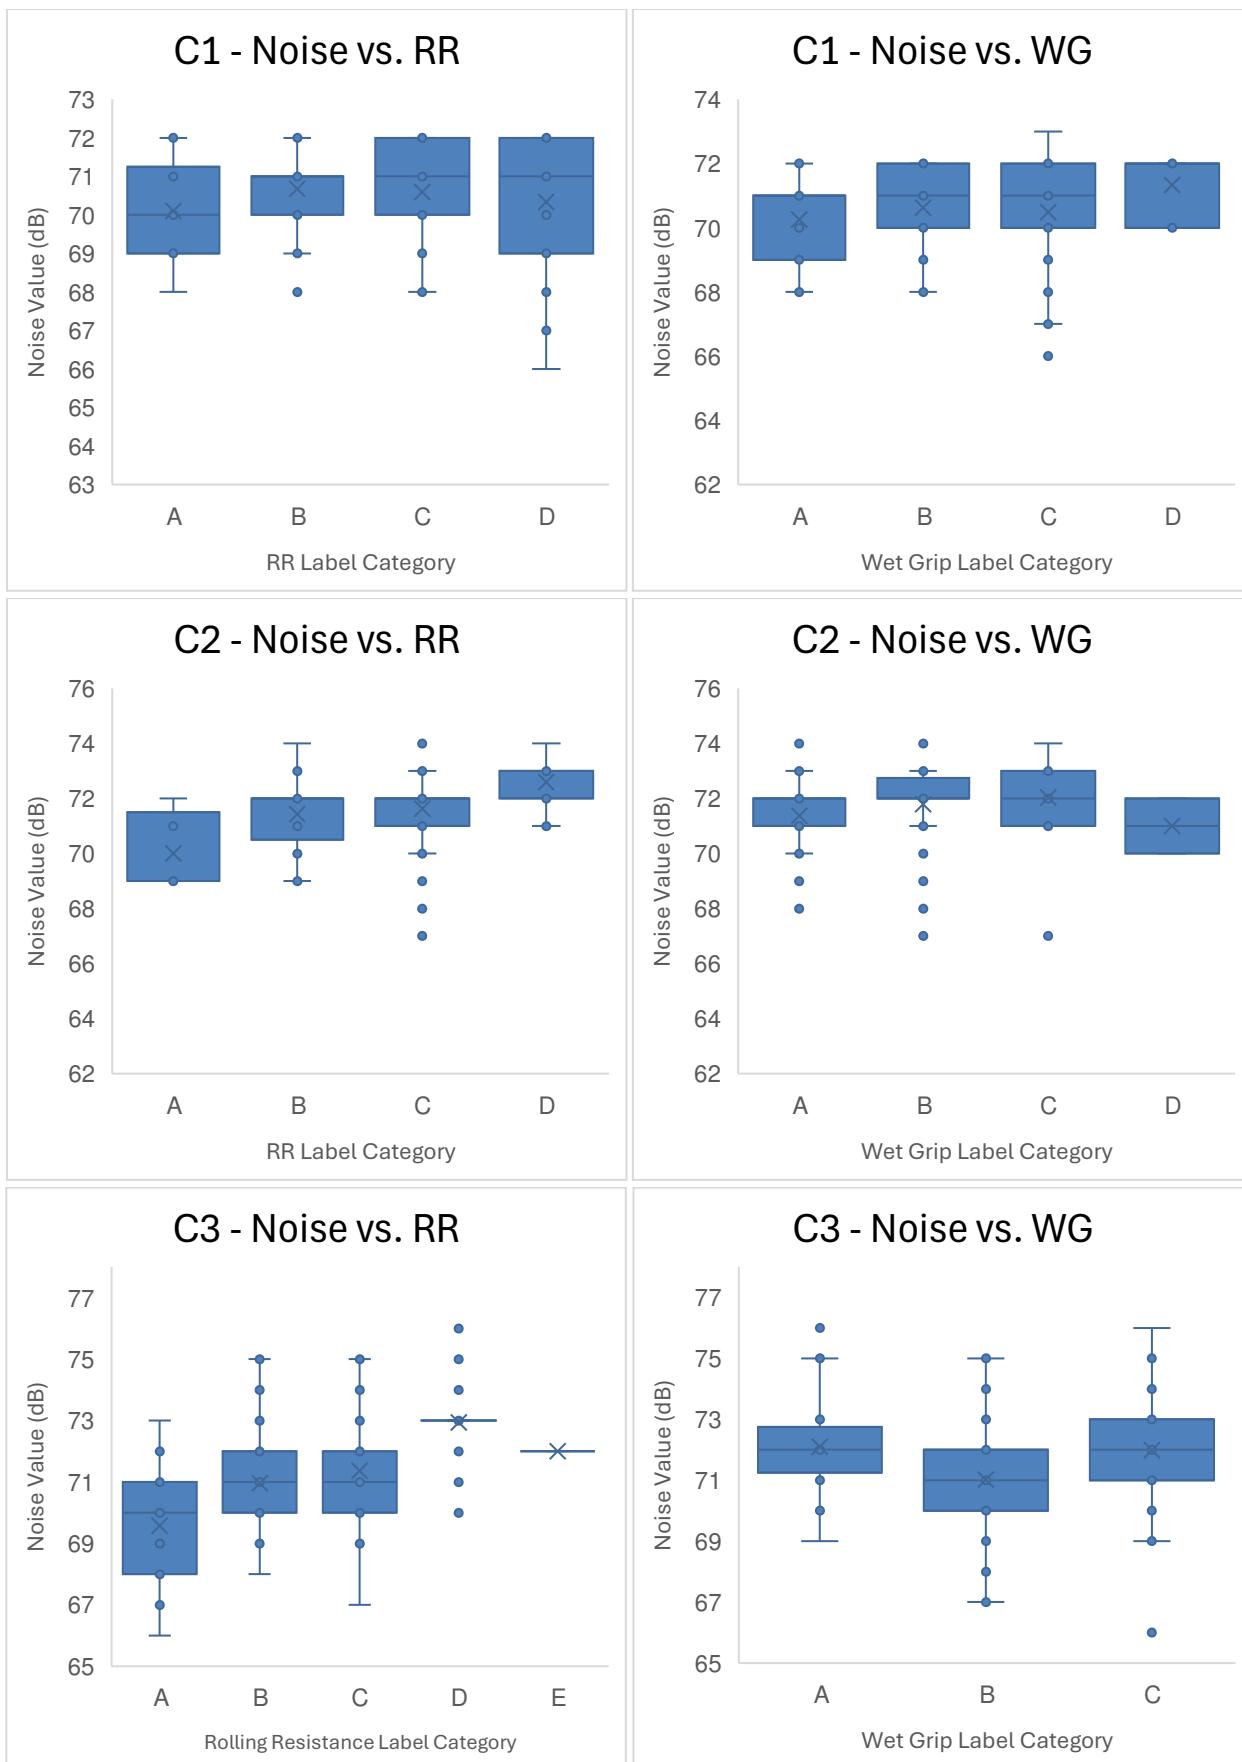

Figure 3 : Noise levels for various RR (left) and WG (right) levels for C1 (up), C2 (middle), C3 (lower) tyres.

8.2.1. C1 tyres

Next tables show relations between RR, WG and noise for various season and tyre sizes.

Table 13 : Relation of RR category and noise levels for season and sizes of C1 tyres.

8.3. Summary

From the previous analysis:

- Average market tyres noise levels: C1: 70.5 dB, C2: 71.7 dB, C3: 71.5 dB

Correlations of the five best selling tyre sizes (all data, seasons, and sizes) showed a tendency of lower noise with improving (lower) letter of rolling resistance (RR) for C1, C2 and C3 tyres. For WG there was no correlation (C2, C3) or lower noise with improving (lower) letter (C1). Thus, in general we do not expect worse performance by lowering the noise of high noise tyres.

A more detailed analysis was not possible due to the lack of detailed info for RR and WG. This will be the topic of the next chapter. However, the general tendency was:

- For C1: With improving (decreasing) RR letter, noise increases (negative). With improving (decreasing) WG letter, noise decreases (positive).
- For C2: With improving (decreasing) RR letter, noise decreases (positive). With improving (decreasing) WG letter, noise decreases (positive).
- For C3: With improving (decreasing) RR letter, noise decreases (positive). With improving (decreasing) WG letter, noise decreases (positive).

Keeping RR and WG the same and correlating noise and tyre price the following trends were found:

- For C1: Lower noise tyres had on average also lower price (2% per dB)
- For C2: Lower noise tyres had on average higher price (2% per dB)
- For C3: Lower noise tyres had on average higher price (6% per dB)

It should also be added that on average, the difference of the maximum noise tyres to the average was 1.5 dB (C1), 1.3 dB (C2) and 2.9 dB (C3) for the EPREL analysis, and 1 dB (C1), 1 dB (C2) and 1.3 dB (C3) for the tyre size specific analysis.

9. Analysis of consumers tyre testing data

The tests were conducted by well-established organizations or magazines (Auto-Motor und Sport, Auto Bild, Auto Zeitung, Allgemeiner Deutscher Automobil-Club (ADAC) and the organization behind the website www.tytereviews.com). Table 19 summarises the sets, number of tyres per set, the parameters that were tested and the organisations that carried out the tests. Although the protocols among different organisations might not be always the same, the tyres of a specific set, tested by the same organisation are comparable. For this reason, each set (i.e. row in Table 19) was analysed separately and then the trends of all sets were combined. In total, 300 tyres from 63 manufacturers were tested, ranging from premium to mid-range to budget brands. The companies with the most tyres tested (50%) were Michelin, Continental, Bridgestone, Goodyear, Falken, Hankook, Maxxis, Nexen, Pirelli. Note that the last set (22) is not from tytereviews.com, but from UTAC on behalf of ACEA [3], and was used only for the abrasion data in this data set. It is separately discussed at the end of this chapter.

20	235/55 R19	11	70.4	68.6	72.8
21	205/55 R16	9	72.2	70.2	74.4
22	245/45R19 102Y	6	71.9	70.2	73.8

For each set, linear regression analysis between noise and a parameter was conducted, in order to see whether the increase of noise will result in higher or lower values of the other parameter. As an example Figure 4 plots noise and abrasion for the only 3 data sets available.

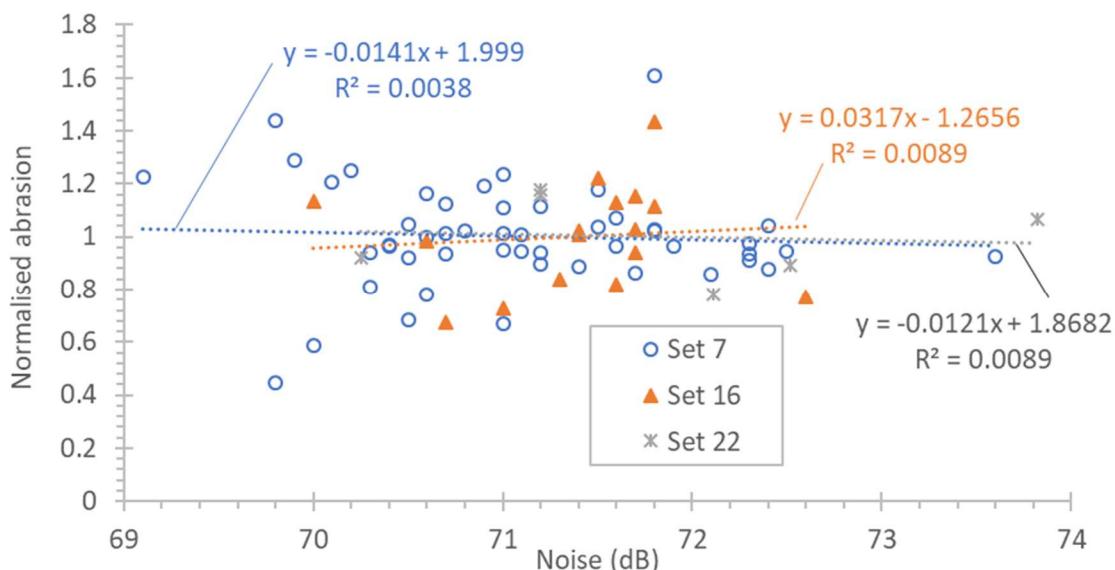

Figure 4 : Correlations between noise and abrasion for three sets of tests.

Next step was to combine all the slopes of all data sets for a specific parameter. Figure 5 plots the average of slopes of all sets available for various parameters (price, rolling resistance, abrasion, mileage). Error bars give one standard deviation. There is no clear effect of reduction of noise to any parameters and in all cases the average goes to the positive side.

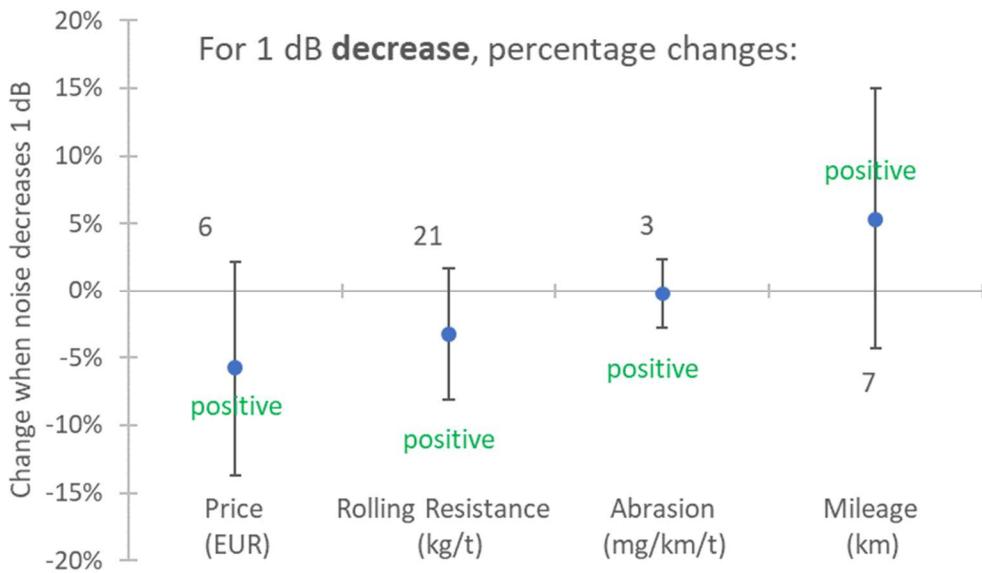

Figure 5 : Impact of lowering noise on various parameters.

Similarly for other safety parameters decreasing noise has a positive impact (Figure 6). However, as the error bars (variability) crosses zero, this impact is not statistically significant. These results demonstrate that current tyres in the market with the current noise levels do not show any impact of noise on other parameters.

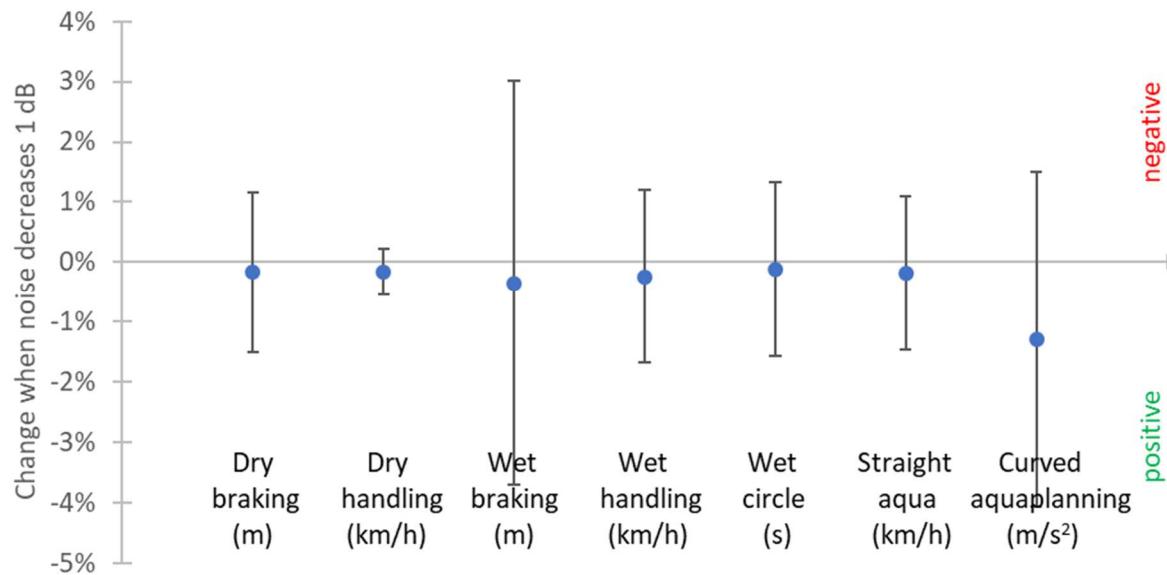

Figure 6 : Impact of noise reduction on various safety parameters.

A dedicated study by UTAC (ACEA) [3] with 16 tyres, based on a statistical analysis, concluded that noise and handling improve together, but there is a conflict between noise and safety performances. No conclusion could be drawn for RR.

10. Noise calculation tool

The cost to human health of noise can be estimated by multiplying the people exposure to high noise levels with the respective costs per dB(A) as given in the Handbook of costs [10]. There are a few studies that have assessed the environmental impact of noise (e.g. ATEEL-ACEA [1], EU projects Heimtsa [4], Venoliva [5], Phenomena [6], M-N noise study [7]). Instead of using the noise exposure of the people moving along daily, noise levels at the facades of the dwellings of the citizens are used as approximations [4]. A good estimation of the actual exposure distribution of EU Member States was reported by the European Environmental Agency (EEA) in the framework of Environmental Noise Directive (END) noise mapping (latest year available 2017) [8]. However, a model is needed in order to assess various mitigation measures. We developed a simplified model combining all previous studies. The model is depicted in Figure 7.

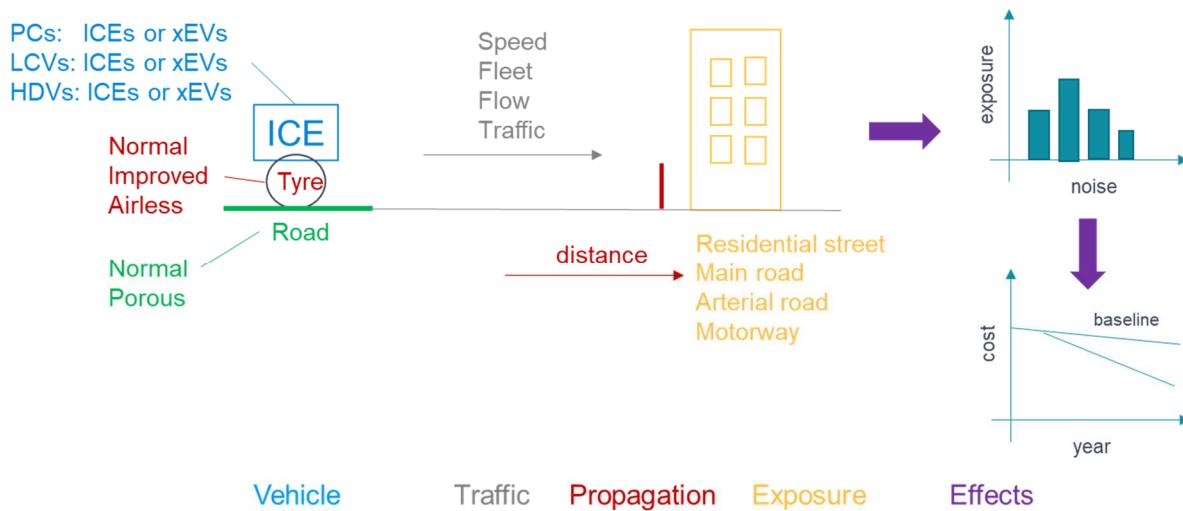

Figure 7 : Schematic representation of the noise calculation model.

The model has five sections: (i) vehicle; (ii) traffic; (iii) propagation; (iv) exposure; (v) effects. The basis of the vehicle model is the CNOSSOS-EU study [9] that estimates the noise emitted by a vehicle depending on the propulsion engine, the tyres rolling noise and the road surface (plus other parameters, such as temperature etc.). However, in our model the initial values are based on the type approval values of tyres and vehicles. This approach has the advantage that any limit changes in the regulations can be directly assessed. The traffic and propagation parts (combined in our simplified model) calculate the noise for various vehicle shares (ICE or electrified), traffic conditions (number of vehicles per hour, average speed, smooth or interment flow) and roads (compared to the ISO surface during type approval or quieter) and propagated to the facades taking into account distance and barriers. The exposure is then calculated based on the population living near various types of roads. Using the cost of noise per dB(A) (from the Handbook on external costs of transport [10]), a cost to the society can be calculated. The calculation can be done for many years assuming various reference conditions: e.g. a specific fleet increase, population increase, electrification penetration etc. From this baseline scenario, various mitigation measures (abatement solutions) can

be assessed by changing one or more parameters (e.g. quieter tyres, quieter surfaces etc.).

The model was ‘calibrated’ with the 2017 END exposure distributions, as extrapolated to EU27 in the M-N study [7, 8]. Then, baseline year was considered 2025 assuming all tyres and vehicles fulfil the latest phases and stages of the regulations (i.e. full compliance with the latest limits). Then the reference scenario assumed only electrification of the fleet. Different scenarios examined various mitigation measures. Details of these steps follow.

10.1. Vehicle

Vehicles are classified to various categories (M1, M2, M3, N1, N2, N3) depending on the number of seats and whether they are designed for carrying passengers or goods. Tyres are classified as C1, C2 and C3. The CNOSSOS-EU model [9], which calculates the noise emissions of individual vehicles, has three vehicle categories light (passenger cars and vans), medium-heavy (vans >3.5 t, busses with two axles), and heavy vehicles (trucks, buses with more than 3 axles).

In order to simplify the categorisation, we considered that C1 tyres are fitted to passenger cars, C2 tyres to light-commercial vehicles, and C3 tyres to heavy-duty vehicles (Table 20). Thus, C1 and C2 tyres are fitted to light vehicles according to CNOSSOS-EU, and C3 tyres to heavy vehicles. For simplification reasons we assumed no medium-heavy category.

Table 20 : Model vehicle category m and tyres categories.

This model	CNOSSOS-EU	Vehicle categories	Tyres categories
PCs	Light vehicles	M1	C1
LCVs	Light vehicles	N1	C2
-	Medium-heavy >3.5 t	M2, M3 and N2, N3	C3
HDVs	Heavy	M2, M3 with trailer, M3, N3	C3

Depending on the available propulsion engine(s), the vehicles in our model are categorized as: (i) only internal combustion engine (ICE); (ii) only electric engine (BEV, FCEV); (iii) hybrids (mild, plug-in PEV)

The simplified model calculates noise $L_{w,m,corr}$ from a vehicle of category m (PC, LCV, HDV) according to this equation:

$$L_{w,m,corr} = L_{w,m} + \Delta L_{intermittent} + \Delta L_{road} + \Delta L_{barrier} + \Delta L_{offset}$$

Where the uncorrected noise of a vehicle $L_{w,m}$ in function of speed v is:

$$L_{w,m}(v) = 10 \log (10^{L_{w,R,m}(v)/10} + 10^{L_{w,P,m}(v)/10})$$

Where $L_{w,R,m}$ is the tyre rolling noise and $L_{w,P,m}$ is the propulsion noise of the vehicle of category m . For $L_{w,R,m}$ we used a simplified formula based on fitting of ACEA data [1] as we wanted to have a function of noise and speed, but based on type approval values.

The curve is similar to our measurements (Chapter 6) and slightly steeper than CNOSSOS-EU:

$$L_{w,R,m}(v) = TA_R + 3 + 35 \log(v/v_{TA,R})$$

The value 3 is due to the higher noise in actual road surface than in type approval ISO surfaces. The type approval speed $v_{TA,R}$ is 80 km/h for C1, C2 tyres and 70 km/h for C3 tyres. We used the stage 2 values for our 2025+ calculations. Only for 2017 we used the stage 1 values (Table 21).

Table 21 : TA_R values used in the model based on UN Reg. 117.

Year	C1 (PC)	C2 (LCV)	C3 (HDV)	
2017	75	75	76	Stage 1
2025 +	71	72	75	Stage 2

For $L_{w,P,m}$ we used fixed values as in the Table 22, independently of the speed. Although there is a small vehicle speed dependence, the engine speed is more important factor; and for typical driving conditions this varies in a small range. This simplification introduces some uncertainty for high and low vehicle speeds; nevertheless not important for the scope of this study. Electric vehicles were assumed to have a propulsion noise of 64 dB(A) based on the lowest measurement (Chapter 5) and not 56 dB(A) (the lowest value in R138). For hybrids we used the average of ICEs and BEVs.

Table 22 : $L_{w,P,m}$ values used in the model based on UN Reg. 51 and UN Reg. 138.

Year	M1 (PC)	N1 (LCV)	M3, N3 (HDV)	
2017	71	73	78	Phase 2 (ICE)
2025 +	69	71	77	Phase 3 (ICE)
2025 +	64	64	64	BEV/FCEV

Note: The table values will underestimate the average noise because they do not consider the higher limits of more powerful vehicle. This underestimation will be covered by the offset.

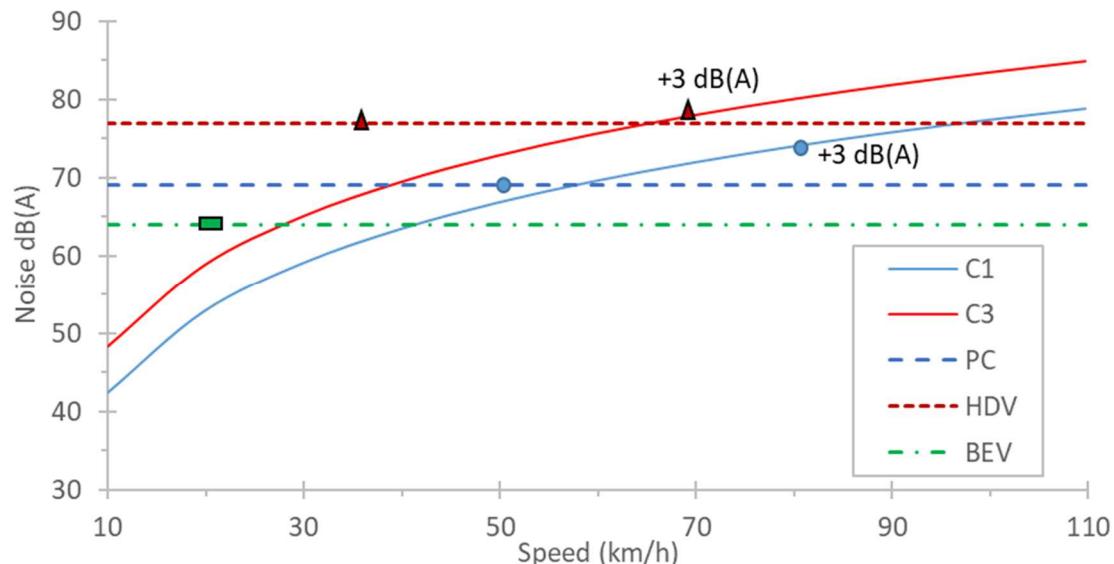

Figure 8 : Noise of tyres (C1 and C3) and propulsion engines (of PC and HDV or BEV) as used in the model. Symbols indicate the speed of the type approval tests for the tyres and propulsion engines PCs (circles), HDVs (triangles) and electric vehicles (square)

From Figure 8, tyre noise becomes significant at high speeds >50 km/h or >40 km/h for electric vehicles. Thus, for high speed roads (motorways) tyre rolling noise plays a major role.

For the rest corrections:

- For **intermittent traffic**, $\Delta L_{intermittent}$, a +3 dB(A) value was added to all vehicles, including BEV/FCEVs. According to CNOSSOS-EU, this correction integrates, in addition to the propulsion engine, the effect of speed variation on tyre noise.
- For the **road surface** effect, ΔL_{road} , we applied subtracted -5 dB(A) for quiet roads.
- For **barriers**, $\Delta L_{barrier}$ we applied a -10 dB(A) correction.
- We also applied an **offset correction**, ΔL_{offset} , of 3.5 dB(A). This (fixed) value was added to bring the year 2017 model results to the END noise urban exposure distribution [8]. It includes noise difference between type approval (ISO tracks) and real roads, temperature, road slope, additional load, different size of tyres effects etc. It also includes uncertainties of the values that were used. For example, we consider C1=69 dB, while the average we calculated was 70.5 (see Chapter 8). Furthermore, we used a single value: the type approval value of one category instead of a distribution of values for all vehicles. Such corrections have been applied to other models as well (M-N [7] and ATEEL [1]) and were of the same order (3 dB for road effect).

10.2. Traffic

The noise of a traffic flow was calculated by the equation provided in the CNOSSOS-EU model, which considers the average velocity v_m and the (steady) traffic flow Q_m for vehicles of category m .

$$L_{w,flow,m} = L_{w,m,corr} + 10 \log (Q_m/v_m/1000)$$

The fleet information are summarised in Table 23 for different periods of the day j (day=8 h, evening=4 h, night=8 h).

Table 23 : Traffic intensities assumed for the noise model. Based on [5].

Road	PC			LCV			HDV		
	Day	Evening	Night	Day	Evening	Night	Day	Evening	Night
1*									
2**	34	25.5	3.4	6.8	3.4	1.7	0.68	1.7	0.85
3*									
4	500	400	50	50	20	5	44	11	5
5	1100	1100	220	121	121	24.2	121	55	33
6***	2500	1875	625	250	187.5	62.5	287.5	182.5	111.3

* Road 1, 3: Increased 25% compared to 2 and 4 respectively due to intermittent traffic

** Road 2: Increased 70% compared to original source

*** Road 6: Increased 25% compared to original source

For the combined flow at a specific period of the day j (day, evening, night):

$$L_j = 10 \log (10^{L_{w,flow,LD}/10} + 10^{L_{w,flow,LCV}/10} + 10^{L_{w,flow,HDV}/10})$$

The long-term average noise indicator is the day-evening-night indicator L_{den} :

$$L_{den} = 10 \log \left(\frac{12}{24} 10^{L_{day}/10} + \frac{4}{24} 10^{(L_{evening}+5)/10} + \frac{8}{24} 10^{(L_{night}+10)/10} \right)$$

Based on previous studies [5, 7], the road types, inhabited length and number of people living (per km) in the model are given in Table 24. The study focused only on urban environments.

Table 24 : Characteristics of urban roads. Based on [5, 7].

	Road type	Traffic	Inhab. length (km)	Inhab./km	Veh/24h	PC km/h	LCV km/h	HDV km/h
1	Residential	Intermit.	643,768	200	835 *	30	30	30
		Free	321,884	200	668	50	40	40
3	Main	Intermit.	66,599	450	11,665 *	40	40	40
		Free	133,197	450	9,332	50	50	50
5	Arterial	Free	94,118	500	23,426	80	80	70
6	Motorway	Free	3,824	1,000	51,820	100	90	90

* It was assumed that with intermittent traffic the vehicle flow is 25% higher than free flow.

10.3. Propagation

No distance correction was applied. The ‘offset’ should include this as well.

As, it was mentioned, for barrier attenuation a mean reduction of -10 dB(A) was applied.

10.4. Exposure

Table 24 presented the people living close to various roads. The numbers were taken from the M-N study [7]. Based on the people living close to roads and the noise calculated for each road category a noise exposure distribution can be found.

EEA reported measured exposure distribution due to road traffic. This was based on END 2017 data. The measured exposure is based on EEA’s report of END 2017 data and was extrapolated to EU27 level at other projects (Heimtsa [4]) and was presented in the M-N study [7]. The assumption is that 334 million people are exposed at urban areas (75% of the EU population). 45% of them (150 million people) are exposed to $L_{den}>55$ dB(A).

Our model was ‘calibrated’ in order to match as possible the measured exposed distribution. The main parameter was the ‘offset’. Slight changes had also to be made at the fleet traffic density. Figure 9 and Figure 10 show the measured and our modelled exposure distribution for 2017.

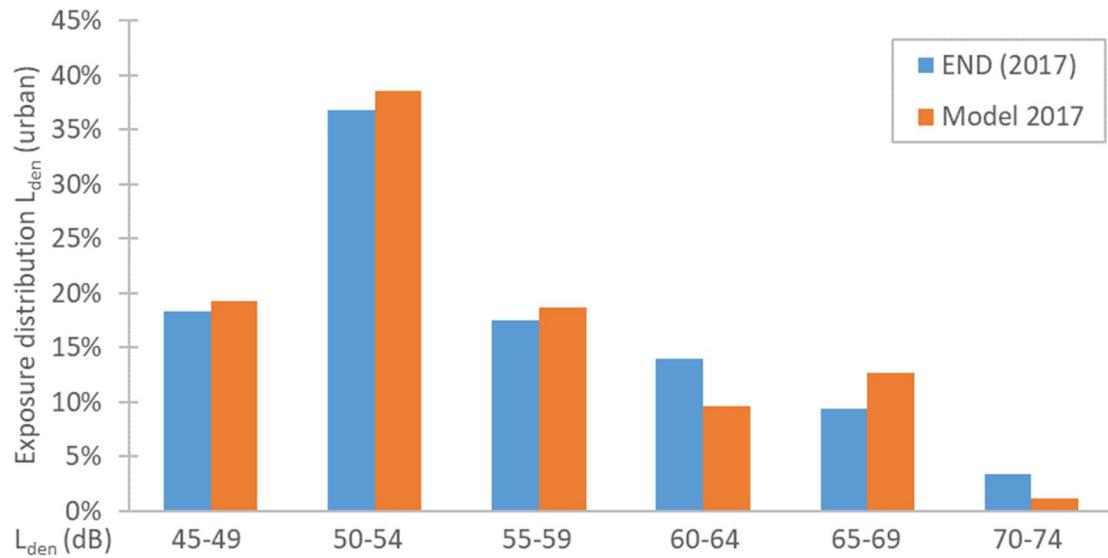

Figure 9 : Noise distributions L_{den} as measured and extrapolated for 2017 (END) and as modelled in this study for 2017.

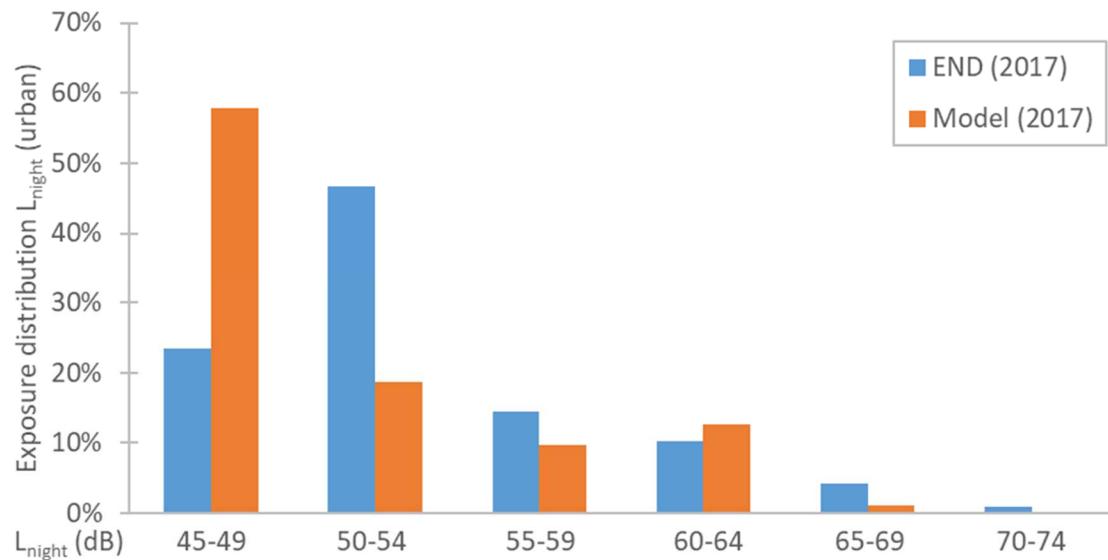

Figure 10 : Noise distributions L_{night} as measured and extrapolated for 2017 (END) and as modelled in this study for 2017.

10.5. Noise costs

The costs were taken from the Handbook on the external costs of transport [10]. It should be added that this methodology, compared to calculations based on people affected and number of healthy life years lost (DALY), gave higher costs by a factor of 2 to 4 in the M-N study. A simple equation was fitted to calculate the costs of traffic noise which include road annoyance and health (in EUR/dB/person/year). The equation is valid for $L_{den} > 50$ dB (0 for lower L_{den}):

$$\text{Cost of traffic noise} = 1.2214 L_{den}^2 - 110.96 L_{den} + 2492.9$$

For administrative, research and development, and production costs we followed the calculation of **Deliverable 6.1**.

10.6. Scenarios

10.6.1. Reference scenario

As it was discussed before, the year 2017 was used only for model calibration. The reference scenario covers from 2025 to 2050. The fleet stock in 2025 was 10% higher compared to 2017. Assuming 0.7% fleet increase per year, the fleet in 2035 was 7.2% higher compared to 2025 and in 2050 19.1% higher than 2025. We assumed that the population increased 0.13% per year based on 2016-2023 data. Furthermore, the impact of higher load (or weight) of the vehicles was not considered, although heavier vehicles tend to be noisier as it is reflected by the tyre and propulsion regulation limits. For example, a study [11] found 0.5 dB higher noise with 25% higher load, a value close to the vehicle mass increase that is expected with fleet electrification. The share of electrified vehicles that we assumed are given in Table 25.

Table 25 : Electrification shares over the years.

Category	Electrification	2017	2025	2035	2050
PC	Hybrids	0%	8%	10%	10%
	BEV/FCEV	0%	5%	30%	85%
LCV	Hybrids	0%	7%	8%	10%
	BEV/FCEV	0%	0%	20%	80%
HDV	Hybrids	0%	0%	5%	10%
	BEV/FCEV	0%	0%	15%	75%

For the reference scenario we assumed that 5% of the length of road #5 had quiet surface and 5% of the length of road #5 had barrier.

10.6.2. Policy scenarios

The following case was examined:

- Quieter tyres -2 dB from 2035

Quieter propulsion engines were not considered as it is expected that ICEs will be phased out. Smooth (free) traffic and quieter road surfaces will be discussed only as they are out of the scope of this study.

10.7. Results

Table 26 summarises the L_{den} noise distributions and the population weighted average. It is clear that the distribution moves to lower noise levels as electrification increases. However, even in 2035, the distribution has not shifted considerably, leaving still the same percentage of the population with noise >55 dB.

D6.3 – Policies and mitigation strategies on tyre noise emissions

Table 26 : Exposure noise distributions. Measured END (2017), model calibration for 2017, calculated from the model from 2025 to 2050.

dB(A)	END (2017)	2017	2025	2035	2050
<50	18.4%	19.3%	19.3%	19.3%	57.8%
50-54	36.8%	38.6%	39.3%	39.3%	0.7%
55-59	17.5%	18.7%	18.7%	18.7%	27.6%
60-64	14.0%	9.7%	21.7%	21.7%	12.7%
65-69	9.4%	12.7%	1.1%	0.0%	0.0%
70-74	3.3%	1.1%	0.0%	1.1%	1.1%
>75	0.5%	0.0%	0.0%	0.0%	0.0%
average	-	56.6	54.6	54.3	52.3

Figure 11 plots the noise evolution over the years with the reference scenario and additional mitigation measures. Already with the fleet electrification significant reductions can be achieved, and mitigation measures further decrease the noise. The L_{den} decreased 3.5% (almost 2 dB) from 2017 to 2025 due to the reduction of noise vehicle and tyre limits (3-4 dB for C1-C2 tyres and 1 dB for C3 tyres, 1-2 dB for the propulsion engines). The additional 20-25% electrification between 2025 and 2030 reduced 0.3 dB the average noise. High degree of electrification (85-95% of the total fleet) reduced the noise almost 2 dB.

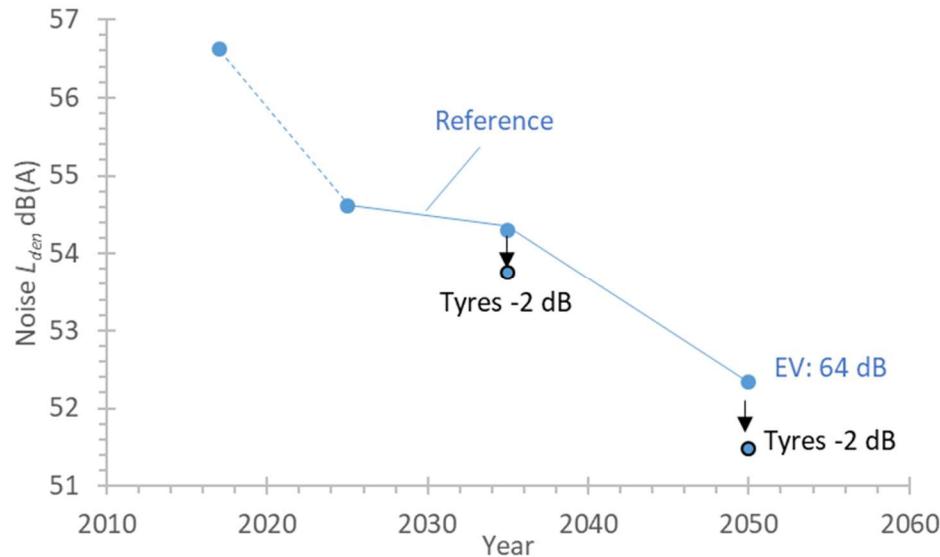

Figure 11 : Population weighted average L_{den} over the years for the reference scenario (blue line) and various mitigation measures.

Figure 12 plots the savings by noise reduction over the years setting 2025 as the baseline year. There is a clear benefit from the noise reduction even for the reference scenario. The savings start to increase slowly with the fleet electrification with 1 bil EUR savings in 2035, and 7 bil EUR only in 2050. Reduction of the tyre rolling noise by -2 dB can save almost 5 bil EUR in 2035 and 6.5 bil EUR in 2050.

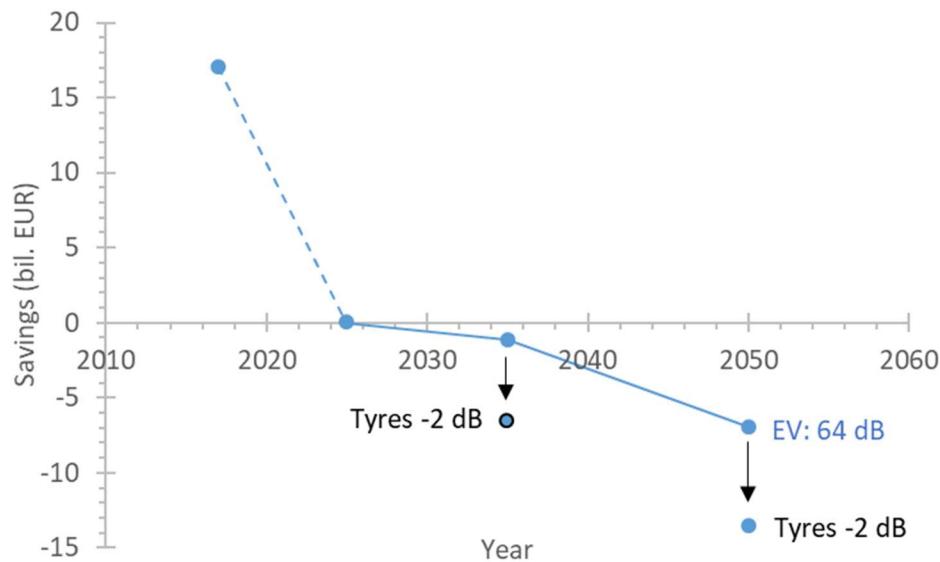

Figure 12 : Savings due to reduce noise compared to year 2025. The reference scenario is the blue line, while other mitigation measures are shown as points.

Regarding costs:

- Testing and administrative: in total 0.3 bil EUR for the period 2025-2050
- Research and development: in total 0.56 bil EUR for the period 2025-2050
- Production (assuming 2% increase of tyres cost of 1/3 of the market tyres): 6.6 bil EUR for the period 2025-2050

It is clear that there is a huge net benefit by noise reductions that by far exceed any costs.

11. Summary

11.1. Data analysis

UN R51 is for vehicles sound emissions and R117 for tyres rolling sound emissions. The main difference on test conditions is the driving condition of full acceleration for R51 compared to coast-by for R117. The target speed in front of the microphones is also different. Combining the average vehicle sound emission and their related tyre average rolling sound emission, we can see the real contribution of the tyres to the total vehicle sound pressure level. Under regulatory conditions, for M1 electric vehicles (quiet vehicles) the tyre has up to 5.6% contribution to the vehicle sound pressure level, while for N3 with internal combustion engine, the tyre has negligible contribution to the vehicle sound pressure level.

Pass-by noise levels were on the order of 71 dB for M1 vehicles, 66 dB for M1 plug-in hybrids, 1-2 dB higher for N1 and N2 vehicles, but around 80 dB for N3. M3 vehicles were on average at 76 dB, and M3 FCEV/BEV 7-9 dB lower.

Regarding the analysis of the label parameters, it is difficult to find a correlation between the labelling parameters, as the tyre's quality level also plays a role. In general, premium tyres tend to show better levels across all label parameters. The average noise levels of the five best selling tyre sizes for C1 tyres were 70.5 dB, for C2 tyres 71.7 dB, and for C3 tyres 71.5 dB. Correlations of all data (all seasons, and sizes) or even separately for each tyre dimension showed a tendency of improved rolling resistance (RR) or wet grip (WG) with lower noise tyres. Thus, in general we do not expect worse performance by lowering the noise of "high" noise tyres (in general reductions on the order of 1 dB). Tyres with the same RR and WG levels showed that lower noise tyres had higher price only for C2 and C3 tyres.

Analysis of the consumers' tyre testing data there is no clear effect of reduction of noise to any parameters (safety, abrasion, RR) and on average the impact was even positive (in general reductions of 1 dB). However, there are studies that show that there is a conflict between noise and safety performances.

11.2. Noise calculation tool

We developed a simplified noise calculation tool combining previous studies. We calibrated the model to the 2017 END noise exposure distributions and applied it to estimate a reference scenario from year 2025 to 2050 and the impact of various mitigation measures. The key characteristics of the model are:

- Tyre rolling noise varies with speed, but the type approval values (of latest Stage 2) are used at the reference regulatory speeds.

- The vehicle noise is fixed and equal to the type approval value (latest Phase 3). For electric vehicles we used a value of 64 dB based on our measurements. Hybrid vehicles were assumed to have noise in between the two (ICE and EVs).
- Intermittent flow increased the noise by 3 dB, quieter road decreased the noise by 5 dB, barriers by 10 dB.
- Based on the traffic conditions (number of vehicles per hour, average speed, smooth or interment flow), road characteristics (quiet, with barrier) and the population living close to roads the noise exposure distribution was calculated.
- Finally, the cost to the society was calculated using the values from the Handbook of road traffic costs.
- The procedure was repeated for every year of interest (from 2025 to 2050) assuming a 0.7% fleet increase, 0.13% population increase, and electrification of the fleet (95% by 2050).

The results clearly demonstrated the decrease of the average L_{den} over the years: 56.6 dB in 2017, 54.6 dB in 2025, 54.3 dB in 2035 and 52.3 dB in 2050. A -2 dB reduction of the tyre rolling noise limits has a -0.6 dB impact in 2035 and -0.9 dB in 2050.

The monetarised savings are large. In the first 10 years the annual savings would gradually reach 1 bil EUR per year, while until 2050 they would reach 7 bil EUR per year only by fleet electrification. Lowering the tyre rolling noise 2 dB would save another 5 bil EUR only in 2035 and another 6.5 bil EUR only in 2050.

11.3. Closing remarks

Based on a WHO review, L_{den} should be below 53 dB and L_{night} below 45. Thus the savings by decreasing noise could be higher than estimated in this study.

The study used the type approval values as actual noise levels (with an offset correction). Studies have pointed a bad correlation and ranking of tyres between type approval surfaces and real road surfaces [13]. While in our study tyre rolling and engine propulsion noise crossed at 50 km/h, other studies find lower speeds (30-50 km/h). Thus the benefits of reducing tyre noise of our study might have been underestimated.

The model assumed that intermittent traffic and quieter roads impact equally rolling and propulsion noise. However this assumption needs to be assessed. It is expected that low-noise road surfaces would have higher impact for rolling noise [1]. In any case, in this study we did not assess the impact of intermittent traffic and quieter roads.

This study did not assess the impact of average speed on noise (e.g. low speed areas with limits of 30 km/h instead of 50 km/h).

This study did not evaluate some mitigation measures such as greening, or fitting buildings with high insulating windows. Such solutions could apply locally in critical areas.

This study did not evaluate non-urban areas. In these areas the average speed is high and the dominant noise source is the tyre, thus fleet electrification will not have a big impact. Other abatement measures such as quieter road and barriers will be more effective (or quieter tyres). Implementation will affect a small percentage of the total (including urban areas) exposed population. Low noise surfaces have slow uptake. Tests with porous surfaces have shown that the surfaces are clogged after only one or two winter seasons, and then the noise reduction is severely reduced [13]. At the moment there is no 'efficiency' index for road surface noise and any assessment is theoretical. A future label for roads could help in a better future evaluation.

Contribution of other sources needs to be assessed, especially as vehicles become less noisy. For example, ETRMA reported that in some cities road transport can be a small percentage of the total noise and L_{den} does not address disturbances as felt by citizens. Local peaks can also contribute significantly.

Some of the measures that have not been assessed need initiatives by the Member States.
